### **ABSTRACT**

In this work, the gamma calibration procedure of the Instruments Calibration Laboratory (LCI) of the IPEN-CNEN/SP was improved with the use of the commercial management software Autolab™ from Automa Company. That software was adapted for our specific use in the calibration procedures. The evaluation of the uncertainties in gamma calibration protocol was improved by the LCI staff and yet the all worksheets and final calibration report lay-out was developed in commercial software like Excell™ and Word™ from Microsft™.

### **1. INTRODUCTION**

The Instruments Calibration Laboratory (LCI) of the IPEN-CNEN/SP calibrates, portable survey meters, ionization chambers, performs irradiation of personal dosimeters (TLD) and calibration of instruments used in dosimetry [1-6] since 1980. These instruments are used in radiation protection, diagnostic radiology and therapy procedures. The costumers of the LCI are hospitals, industries, clinics, universities and others in Brazil and some South America countries. The LCI is a calibration laboratory inside the Radiation Metrology Center (CMR) of the IPEN. In the last years, the number of portable survey meters calibrated for the Instruments Calibration Laboratory (LCI) of the IPEN-CNEN/SP was increased continuously; in 2006, about 1,600 equipments were calibrated. An optimization of the gamma calibration protocols was necessary to attend the new service demand.

The LCI has special reference systems for calibration and dosimetry in radiation protection, diagnostic radiology and radiotherapy levels. To the establishment of the radiation qualities beams for the calibration of the portable survey meters (such as Geiger-Müller, scintillators, ionization chambers and semiconductors) and instruments used in dosimetry, the LCI uses as a reference a secondary standard spherical ionization chamber connected to an electrometer, and the gamma irradiator system has Cs-137, Co-60, Ra-226 and Am-241 radioactive sources.

The whole calibration procedure has many steps such as administrative steps (management of the calibration schedule and pricing, final report printing and safety copy, archive in paper of the whole forms used in the calibration process, etc.), and technical steps (calibration set-ups

and procedures, environmental condition control, reference system measurements, uncertainties evaluation, fill out calibration worksheets, etc.). Considering the difficulty in upgrading the set-ups and staff of the LCI, an improvement of the whole calibration process is very helpful. When one thinks in improve a process the first idea is change parts or cut steps in the process but, when it is not possible to cut steps of the process it is necessary to verify what it is possible to change in each step to improve the process. The second very good idea is to modify the speed of the whole process doing the steps and the whole process very fast. In that case, the study of a special commercial software to the management of the whole calibration process with advantages in the regular calibration process is desirable in order to improve the quality and speed in the whole process, transferring safely the calibration data, clients information and back-up of the all steps during the calibration procedures. That specific software would solve the difficulties coming with the increased calibration demand in the LCI.

Then, the objective of this work was study the whole calibration process (step by step) of the gamma portable survey meters adapting the commercial software to improve the whole calibration procedures of the LCI.

## 2. MATERIALS AND METHODS

For the study of the whole calibration procedures were used a commercial software for manager the calibration procedures including calculation routines (Autolab<sup>TM</sup>) [7]; the gamma irradiator system from manufacturer STS Steuerungstechnik & Strahlenschutz GmbH, Germany, with Co-60 (18,0 GBq), Cs-137 (651 GBq), Am-241 (7,3 GBq) and Ra-226 (0,4 GBq) radioactive sources, the reference date of the sources is December 2005. The gamma radiation qualities established follow the recommendations of the Standard ISO 4037-1[8], radioprotection level. For dosimetry of the gamma calibration system was used a reference system with PTW 32002, ionization chamber (1.000 cm<sup>3</sup>) connected to a PTW electrometer, model UNIDOS, check-source of the Sr-90, and others instruments such as, thermometer, barometer, hygrometer, etc.

The calibration procedures review was made and included all steps: management of the calibration schedule and pricing; storage of the equipments; calibration set-ups; environmental conditions control; reference system measurements; uncertainties evaluation and calibration report.

The chosen commercial software was Autolab<sup>TM</sup> from Automa Company. Its structure allows the use of the modules such as: calibration schedule, quotation service, calibration data sheets, uncertainties evaluation, automatic writing of the calibration report, data base of the equipments models and calibration protocols, etc. However, that software was developed for use in electrical measurements and not specific for radiation measurements, then it was necessary an adaptation in that modules. The evaluation of the uncertainties in gamma calibration protocol was improved as recommended for ISOGUM [9], the worksheets developed in the commercial software Excell<sup>TM</sup> received a new lay-out, and the final calibration reports received a new design with essential information for the clients [10].

## 3. RESULTS

As the initial step of the calibration procedures review was made the inventory of the instruments calibrated for LCI in the last five years, and the results show that were tested about 500 different models (80 % with operational manuals); 17,7 % from Brazilian manufactures and 82,3 % from others countries. One inventory and re-organization of operate and service manuals archive was made to help in the inventory of those instruments (their location, identify tag, number of copies, etc.). The Table 1 shows the 20 models of equipments most calibrated for LCI in 2006 from a total of the 200 calibrated models, ordered by the percentage (%) of each kind of equipment calibrated.

**Table 1. Numerical results of the instruments calibrated for the LCI in 2006**

Manufacturer	Model	Manual status (Yes/No)	Number of instruments calibrated in 2006 (units)	In percentage of the total instruments calibrated (%)
Ludlum	3	Y	59	6,06
MRA -Nacional	G1Plus	N	29	2,98
Victoreen/Inovision	190	Y	29	2,98
Arrow-Tech	138S	N	26	2,67
Automess	6150AD	Y	25	2,57
Dosimeter	862	Y	24	2,46
Radcal	9015	Y	23	2,36

For the evaluation of the uncertainties in gamma calibration protocol all uncertainties factors were determined, such as,  $\mu_{kar}$  is the uncertainty in air kerma rate;  $\mu_{Ld}$  is the uncertainty in dosimeter indication;  $Ci_{ld}$  is the sensibility coefficient for Ld;  $\mu_{FC}$  is the uncertainty in calibration factor;  $Ci_{FC}$  is the sensibility coefficient for FC;  $\mu_{tp}$  is the uncertainty in temperature and atmospheric pressure factor;  $Ci_{itp}$  is the sensibility coefficient for ftp;  $\mu_t$  is the uncertainty in time of charge collection of the electrometer;  $Ci_t$  is the sensibility coefficient for t. The equation 1 shows the expression for the uncertainty evaluation in the air kerma rate for gamma irradiation system of the LCI, used for calibration of the portable survey meters.

The Table 2 shows the results obtained of the uncertainty evaluation in the air kerma rate for gamma irradiation system of the LCI, for the Cs-137 source.

$$\mu^{kar*} = \mu^{Ld*} \times Ci^{ld*} + \mu^{FC*} \times Ci^{FC*} + \mu^{fp*} \times Ci^{fp*} + \mu^{t*} \times Ci^{t*} \quad (1)$$

Where \* is exp +02

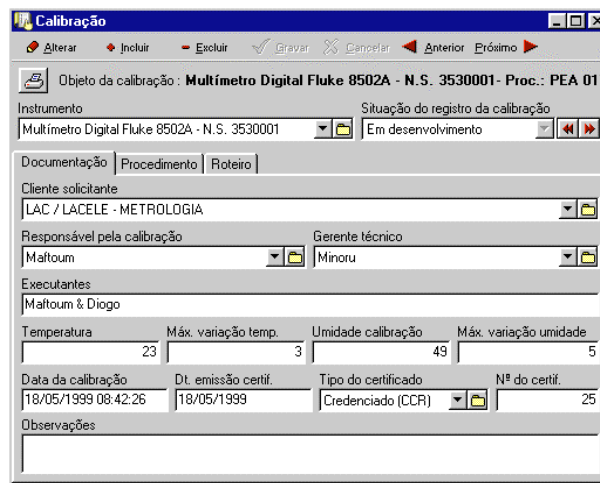

**Table 2. Uncertainties evaluation of the air kerma rate for radioactive source of Cs-137 for the STS gamma irradiator of the LCI (IPEN-CNEN/SP)**

Distance from the center of the irradiator (cm)	Air kerma rate (mGy/h)	Uncertainty* (mGy/h)	Relative uncertainty* (%)
75	80.45	1.14	1.42
120	30.40	0.44	1.45
126.9	27.31	0.39	1.43
226.9	8.47	0.12	1.42
326.9	4.05	0.06	1.48
426.9	2.37	0.04	1.69

\* Coverage factor k = 2 (95.45 %)

The Table 2 shows that the air kerma rate obtained follows the inverse square law of distances, and the main uncertainty component is the uncertainty of the calibration factor. The uncertainties obtained for the Co-60 source are very close to the results for the Cs-137 source.

The Figure 1 to 3 show the Autolab™ worksheets (protocol, calibration and calibration uncertainties) that should have some modifications to reach a final lay-out, and need to receive some adjusts to attend the specific application of the LCI-IPEN. It is necessary to do a continuously improvement of that.

## 4. CONCLUSIONS

The great advantage of that software system is: the automatic transfer of the calibration worksheets and client information to the calibration report after the finished calibration procedures and a central data base of all calibration information. That process improved operates with a main microcomputer (server) in a computer network. That system improves the quality of the data and information (reduces writing mistakes, change of the information, reduces costs like re-work, few paper printed, etc.) and increase the speed of the whole calibration process (reducing in about 15 % the time spend in that calibration procedures).
