Keywords: HTPEMFC, DEFC, PBI, ethanol electro-oxidation, Carbon Nano Fiber

The high-temperature proton-exchange membrane fuel cells (HTPEMFCs), which can operate between 120 and 180°C, suggest many applications since as a small to medium scale emergency power supply unit and an alternative power source for small scale applications until combined heat and power (CHP) systems for residential and small commercial, militaries and vehicles applications. Direct ethanol fuel cell (DEFC) has advantageous features such as high power density, low weight, compactness, and suitability for discontinuous operation. [1] However, the relatively complex reaction mechanism in the DEFC makes the subject of many studies [2].

In this work, catalysts based on PtRu (1:1), supported on carbon nanofibers for the electro-oxidation of ethanol were prepared by two different methods, sodium borohydride and alcohol-reduction processes. They were characterized by X-ray diffraction, SEM-EDX, TEM and temperature programmed reduction. Moreover, essays in a H₃PO₄ doped polybenzimidazole (PBI)-based fuel cell operating at 125–200 °C were carried out to evaluate the performance of the catalysts prepared.

Acknowledgement

The authors thank the Junta de Comunidades de Castilla-La Mancha through the Project PBI08-151-2045 and to Ministerio de Ciencia e Innovación, Spain, (CTM2007-60472) for the financial support. The University of Castilla-La Mancha is also acknowledged for the grant awarded to Mr. Verjulio-Silva
