ABSTRACT

Gaining prominence in clinical practice, the ⁶⁸Ga, positron emitter radionuclide easily obtained by ⁶⁸Ge/⁶⁸Ga generator elution, has shown potential and excellent quality on radiolabeling of peptide for use in positron emission tomography (PET), in particular urea-based inhibitor peptides, directed to the prostate-specific membrane receptor (PSMA). Previous studies with the PSMA linked to the chelator HBED-CC (PSMA-11) radiolabeled with ⁶⁸Ga showed high contrast PET/CT images to evaluate recurrence and metastasis of prostate cancer, becoming an important imaging agent in the clinical routine. This work intended to evaluate the influence of the quality of the ⁶⁸Ge/⁶⁸Ga generator eluate in direct labeling of PSMA-11 with ⁶⁸Ga, assisting in the development of kit for prompt radiolabeling. It was evaluated the ⁶⁸GaCl₃ eluate from ⁶⁸Ge/⁶⁸Ga non-GMP generator (manufacturer A) and ⁶⁸Ge/⁶⁸Ga GMP generator (manufacturer B), both commercially available. To evaluate the influence of the ⁶⁸Ga eluate on radiochemical yield of the preparations, the radiochemical purity was determined by thin layer chromatography and HPLC. The radiolabeling with non-GMP generator eluate was determined with and without preliminary purification of the 68 gallium chloride eluate, employing cationic purification columns. The results showed higher radiochemical yield with the ⁶⁸GaCl₃ eluate from the ⁶⁸Ge/⁶⁸Ga GMP generator, obtaining the radiolabeled product more easily and speed to clinical practice, without preliminary purification, as opposed to the use of non-GMP ⁶⁸Ge/⁶⁸Ga generator which required preliminary purification of the ⁶⁸GaCl₃ eluate to promote satisfactory radiochemical purity results.

1. INTRODUCTION

According with the World Health Organization (WHO) data for 2018, cancer has become the main cause of the decrease in the life expectancy in the world, overcoming the numbers of deaths from coronary heart disease and stroke. The causes are still controversial, however, according to studies conducted, the risk factors depend on regional socioeconomic development. (Bray *et al*, 2018)

In the ranking, prostate cancer is the second most incidence in men, presenting 1.276,106 new cases of pathology in 2018, according to data collected by GLOBOCAN. (Bray *et al*, 2018)

For the years 2018 and 2019, data raised by INCA suggest the incidence of 600 thousand new cases of cancer in Brazil for each year, putting prostate cancer among the most incident cancers. (INCA, 2017)

With greater occurrence in men of the old age, the prostate cancer still has no definite causes. Anatomically, the prostate is a gland located in the lower part of the bladder, composed of a fibromuscular stromal network, vascular endothelium, immune cells and several other cell

types organized rearrangement in an epithelium. This heterogeneity of the gland makes it difficult to elucidate the causes of the pathology. (Packer, 2016)

Among diagnostic methods with greater specificity and sensitivity, the diagnostic imaging tests used in nuclear medicine with the administration of radiopharmaceuticals present great advances, since the clinical practice is confronted with controversial results in the tests of touch and serum dosage of PSA, generating false-negative results, which decreases the reliability of these results and delays the early diagnosis. (Afshar *et al*, 2015)

The PSMA (prostate specific membrane antigen), a type II transmembrane protein, is overexpressed and present in 95% of cases of prostate cancer. (Miyahira, 2018)

The continuous internalization through migration between the cell membrane and the cytoplasm, makes the PSMA a therapeutic target, when in the presence of binding molecules. (Miyahira, 2018)

Considering this characteristic, radiotracers targeting PSMA are being studied for acquisition of diagnostic imaging of prostate cancer in PET, in particular the PSMA linked to the bifunctional chelator HBED-CC (PSMA-11) radiolabeled with ⁶⁸Ga.

Easily obtained by elution of ⁶⁸Ge/⁶⁸Ga generators and with a physical half-life of approximately 68 minutes, the ⁶⁸Ga radionuclide has been widely used in nuclear medicine for imaging diagnostic tests on PET equipment. The eluate obtained from the generators facilitates clinical routine and assists in delivering the product to clinics away from centers producing cyclotron radiopharmaceuticals. (Velikyan *et al*, 2014)

The eluate from the ⁶⁸Ge/⁶⁸Ga generator has metallic impurities that, if not removed, can compete with ⁶⁸Ga in solution decreasing the percentage of radiochemical purity of the final product. In its composition the ⁶⁸Ge may be immobilized on an alumina column, tin or titanium dioxide, being able to elute ⁶⁸Ga with 0.1 M, 0.05 M or 1 M HCl, depending on the generator model used. (Banerjee *et al*, 2013)

This work studied the influence of the eluate of ⁶⁸Ge/⁶⁸Ga generators from two different manufacturers on the labeling yield of a kit for ready labeling of PSMA-11 under development.

2. MATERIAL AND METHODS

2.1. Previous Radiolabeling Study

The assays and parameters of radiolabeling were initially based on the kit developed by POLATOM (Poland), for radiolabeling of PSMA-HBED-CC with ⁶⁸Ga, containing 20 μg of the PSMA-HBED-CC peptide and sodium acetate in the formulation. The radiolabeling instruction of the kit provides the use of 5 mL of ⁶⁸GaCl₃ and 10 minutes at 90 °C. The radiolabeling conditions were evaluated for different elutions of ⁶⁸Ge/⁶⁸Ga generators from manufacturer A and manufacturer B, corresponding respectively, to a non-GMP ⁶⁸Ge/⁶⁸Ga

generator, with a titanium oxide column, eluted with HCl 0.1 M and a ⁶⁸Ge/⁶⁸Ga GMP generator with silica column, eluted with 0.05M HCl.

In this work, the radiolabeling buffer was studied. The sodium acetate buffer was prepared in different molar concentrations evaluated against different volumes of of 0.1 M HCl and 0.05 M HCl solution, employed in the elution of commercially available ⁶⁸Ge/⁶⁸Ga generators.

For all experiments developed, ⁶⁸Ge/⁶⁸Ga generator from manufacturer A was eluted with 0.1M HCl and the generator of manufacturer B was eluted with 0.05M HCl to obtain 5 mL of ⁶⁸GaCl₃.

2.2. Chromatographic Radiochemical Purity Test

The chromatographic profile of ⁶⁸GaCl₃ and the radiolabeling mixture was studied in two systems: (1) Thin-layer chromatography with mobile phase citrate buffer:citric acid 1M (v/v), pH 5, and mobile phase methanol:ammonium acetate 1M (v/v), pH 8.5 in chromatographic supports of ITLC-SG and TLC-SG and (2) High Performance Liquid Chromatography (HPLC) - Mobile phase A: trifluoroacetic acid:water for chromatography (1:999 v/v). Mobile phase B: trifluoroacetic acid:acetonitrile (1:999 v/v). Stable phase column of octadecylsilyl silica gel for chromatography, 3 mm in diameter and 0.15 m wide. The solvent concentration gradient is described in Table 1. (Gallium (⁶⁸Ga) PSMA – 11 injection, European pharmacopoeia)

Table 1: Solvent concentration gradient described by the European pharmacopoeia for ⁶⁸Ga-PSMA 11. (Gallium (⁶⁸Ga) PSMA – 11 injection, European pharmacopoeia)

Tempo (min)	Fase móvel A (v/v)	Fase móvel B (v/v)
0 - 0.5	95	5
0.5 - 10	95 - 60	5 - 40
10 - 11	60 - 95	40 - 5
11 - 16	95	5

2.3. Non-Automated Radiolabeling of PSMA-HBED-CC With ⁶⁸GaCl₃ Eluted From ⁶⁸Ge/⁶⁸Ga Generator of Manufacturer A Without Prior Purification

Six labels were performed employing ⁶⁸GaCl₃ without prior purification under the conditions described above. The range of activity employed in the radiolabeling was 333 to 370 MBq (9 to 10 mCi).

2.4. Non-Automated Radiolabeling of PSMA-HBED-CC With ⁶⁸GaCl₃ Eluted From ⁶⁸Ge/⁶⁸Ga Generator of Manufacturer A With Prior Purification

Radiolabeling was performed with prior purification of the eluate from the ⁶⁸Ge/⁶⁸Ga generator of manufacturer A in a cationic cartridge identical to that used in the automated

modules for the synthesis of 68 Ga-DOTATATE. The 68 GaCl₃ solution was passed through the cationic cartridge, the eluate was scorned as it dragged the chemical and radionuclide contaminants from the eluate and gallium-68 was eluted with 800 μ L of acid acetone solution. The volume of this eluate was completed to 5 mL with 0.1M HCl.

This purified 68 GaCl₃ solution was transferred to a labeling flask containing 20 µg of PSMA-HBED-CC and 1 mL of 1.5M sodium acetate buffer pH 6. The final solution was heated in block heater for 10 minutes at 90 ° C. The final solution of the radiolabeled product presented pH 5. The range of activity employed in the radiolabeling was 222 to 370 MBq (6 to 10 mCi). The radiochemical purity of the labels was determined using the previously described CCD / ITLC-SG method.

In order to remove the turbidity of the labeling mixture and to determine as it influences the radiochemical purity, the filtration of the final radiolabeled product was performed in a $0.22~\mu m$ filter membrane. The radiochemical purity of the labels was determined using the previously described CCD / ITLC-SG method.

2.5. Non-Automated Radiolabeling of PSMA-HBED-CC With ⁶⁸GaCl₃ Eluted From ⁶⁸Ge/⁶⁸Ga Generator of Manufacturer B

The radiochemical purity of the labeling was also studied using ⁶⁸GaCl₃ solution eluted from ⁶⁸Ge/⁶⁸Ga generator from manufacturer B, GMP, without previous purification. The elution was performed with 5 mL of 0.05 M HCl, according to manufacturer's specification. The radiolabeling was performed under the same conditions described above, with the final product having pH 5. The range of activity employed in the radiolabeling was 148 to 222 MBq (4 to 6 mCi). No turbidity was observed. The radiochemical purity of the labels was determined using the previously described CCD / ITLC-SG method.

3. RESULTS AND DISCUSSIONS

The evaluation of the chromatographic systems used in the determination of the radiochemical purity in thin layer chromatography showed that the mobile phase methanol: ammonium acetate 1M (v / v) pH 8.5 retains the free 68 GaCl₃ species at the origin of the plate, allowing the labeled product to migrate to the end of the chromatographic plate, and performing the separation of the radiochemical species. The same does not happen with the mobile phase citrate buffer:citric acid 1M (v / v) pH 5, whereas in this system the 68 GaCl₃ migrates to the end of the chromatographic plate as the labeled product. The two chromatographic supports of thin layer chromatography presented the same profiles and the ITLC support was chosen for finalizing the chromatographic run in only 30 minutes.

The mean percentage of radiochemical purity (% PR) of six non-automated radiolabeling of PSMA-HBED-CC using generator eluent from de manufacturer A without prior purification, evaluated in thin layer chromatography, was 28.0 ± 7.4 %. The low radiolabeling yield is probably related to the presence of high levels of trivalent metals in the generator eluate, in addition to a percentage of 68 Ge above the limit specified in the European Pharmacopoeia.

Figure 1 shows the chromatographic profile in CLAE of the radiolabeling mixture using ⁶⁸GaCl₃ without prior purification.

INAC 2019, Santos, SP, Brazil.

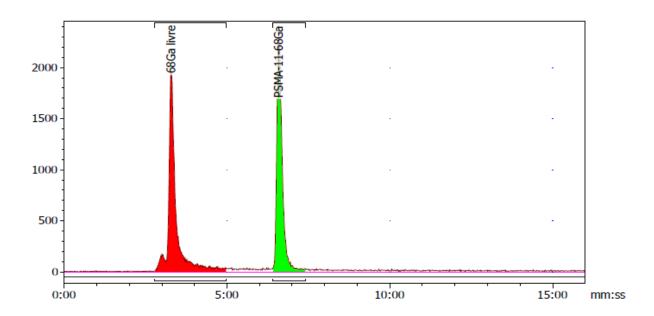

Figure 1: Profile of PSMA-HBED-CC labeled with ⁶⁸GaCl₃ eluted from ⁶⁸Ge/⁶⁸Ga generator from manufacturer A, without prior purification, according to the previously described method.

In the six non-automated PSMA-HBED-CC radiolabeling developed with 68 GaCl₃ eluted from the manufacturer's generator A and previously purified on a cationic resin column, the mean percentage of radiochemical purity analyzed in thin layer chromatography / ITLC-SG was 81.6 ± 7.4 %, showing a significant increase when compared to labeling without purification, but still below the percentage specified in the proposed European Pharmacopoeia monograph (> 91%).

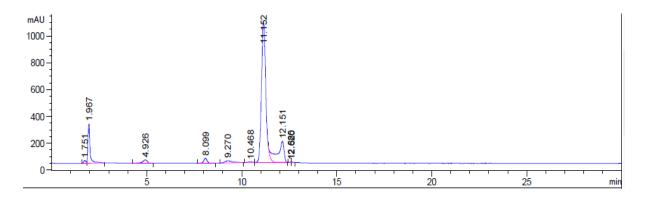

Figure 2: Profile of PSMA-HBED-CC labeled with ⁶⁸GaCl₃ eluted from ⁶⁸Ge/⁶⁸Ga generator from manufacturer A, previously purified on a cationic resin column.

The final solution of the labeled product also presented slight turbidity, which was removed after filtration of the radiolabeling mixture in the 0.22 μ m filter membrane. The filtration promoted an increase in the mean radiochemical purity percentage to 92.5 \pm 1.3 %. Thus, the use of non-GMP generator eluate only achieved satisfactory results of radiochemical purity when the eluate was previously purified on a cationic column to remove

excess metal and 68 Ge contaminants and the final product was filtered on a 0.22 μ m membrane, conditions that simulate the radiolabeling on automated synthesis module.

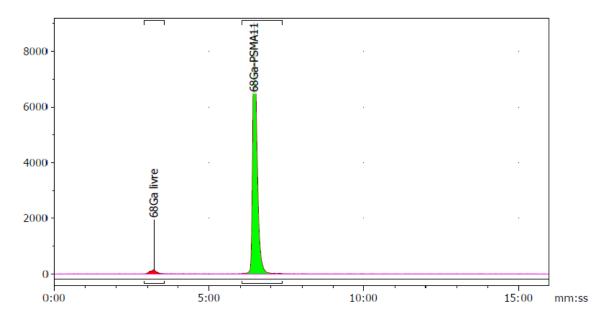

Figure 3: Profile of PSMA-HBED-CC labeled with ⁶⁸GaCl₃ eluted from ⁶⁸Ge/⁶⁸Ga generator from manufacturer A, previously purified on a cationic resin column and filtered on a 0.22 µm membrane.

On the other hand, considering the non-automated radiolabeling of PSMA-HBED-CC with $^{68}\text{GaCl}_3$ eluted from the $^{68}\text{Ge}/^{68}\text{Ga}$ generator from manufacturer B, GMP, the results showed a percentage of radiochemical purity of 91.0 ± 1.5 % (N=2), according to the pharmacopoeial specification, without the need for prior purification of the eluate. In this case, the radiolabeling mixture appeared clear.

The acid solution of gallium chloride eluted from the GMP generator meets the pharmacopoeial specifications for the limits of ⁶⁸Ge and metallic contaminants, allowing the use in direct radiolabeling procedure, using kits for ready radiolabeling and without the use of automated synthesis module, since labeling results in radiochemical purity meets the pharmacopoeial criteria without the need for further purification.

4. CONCLUSIONS

This study demonstrated that the non-automated labeling of PSMA-HBED-CC with ⁶⁸Ga, using a direct method that with a proposed kit for ready radiolabeling resulted in a satisfactory radiochemical purity percentage only when using ⁶⁸Ge/⁶⁸Ga grade GMP generator eluate demonstrating the importance of the use of generator eluate that meets the pharmacopoeial purity criteria, especially in non-automated direct labeling.
